Schedule

Week 3 (18–22 October):

- **Lecture 5:** Classical probability I (Monday 17 October)
- **Lecture 6:** Classical probability II (Wednesday 19 October)
- **Problem Sheet 1:** Work through the short and long questions in preparation for your tutorial in Week 4. Deadline for assessed questions: Monday 31 October.
- **R Worksheet 3:** Data in R to be completed this week. Deadline for assessed questions: Monday 24 October.

Week 2 (10–14 October):

- **Lecture 3:** Sample spaces and events (Monday 10 October)
- **Lecture 4:** Probability (Wednesday 12 October)
- **Tutorial:** to discuss Problem Sheet 1; check your timetable for details.
- **Problem Sheet 1:** Work through the short and long questions in preparation for your tutorial. Deadline for assessed questions: Monday 17 October.
- **R Worksheet 2:** Vectors to be completed this week.

Week 1 (3–7 October):

- **Lecture 1:** Summary statistics (Monday 3 October)
- **Lecture 2:** Data visualisation (Wednesday 5 October)
- **Problem Sheet 1:** Work through the short and long questions in preparation for your tutorial in Week 2. Deadline for assessed questions: Monday 17 October.
- **R Worksheet 1:** R basics to be completed this week.

About MATH1710

Organisation of MATH1710

This module is **MATH1710 Probability and Statistics I**. (It is possible to take this module as half of **MATH2700 Probability and Statistics for Scientists**, but I am not aware that any students are enrolled on MATH2700 this year – please let me know if you are.)

This module lasts for 11 weeks from 3 October to 16 December 2022. The exam will take place between 16 and 27 January 2023.

The module leader, the lecturer, and the main author of these notes is Dr Matthew Aldridge (you can call me “Matt” or “Dr Aldridge”, pronounced “*old-ridge*”).

Lectures

The main way you will learn new material for this module is by attending lectures. There are two lectures per week. Because this is a very large class, you are split into two groups for lectures:

- Group 1: Mondays at 1200 and Wednesdays at 1600
- Group 2: Mondays at 1500 and Wednesdays at 1500

All lectures are in Roger Stevens LT 20. Check your timetable to see which group you are in.

I recommend taking your own notes during the lecture. This website will keep brief notes from the lectures, summarising the main definitions and theorems, but will not reflect all the details I say and write during the lectures. Lectures will go through material quite quickly and the material may be quite difficult, so it’s likely you’ll want to spend time reading through your notes after the lecture.

You are probably reading the web version of the notes. If you want a PDF copy (to read offline or to print out), it can be downloaded via the top ribbon of the page. (Warning: I have not made as much effort to make the PDF as neat and tidy as I have the web version, and there may be formatting errors.)

I am very keen to hear about errors in the notes, mathematical, typographical or otherwise. Please email me if think you may have found any.

Attendance at lectures is compulsory.

Problem sheets

There will be 5 problem sheets. Each problem sheet has a number of short and long questions for you to cover in your own time to help you learn the material, and two assessed questions, which you should submit for marking. The assessed questions on each problem sheet make up 3% of your mark on this module, for a total of 15%. Deadlines are 2pm on Mondays, although I'd personally recommend completing and submitting the work in the previous week.

Problem Sheet	Lectures covered	Deadline for assessed work
1	1 and 2	Monday 17 October (Week 3)
2	3–6	Monday 31 October (Week 5)
3	7–10	Monday 14 November (Week 7)
4	11–14	Monday 28 November (Week 9)
5	15–18	Monday 12 December (Week 11)

An informal Problem Sheet 6 covering material from Lectures 19 and 20 will be available; Lectures 21 and 22 are revision lectures with no new material.

Assessed questions should be submitted in PDF format through Gradescope. (Further Gradescope details will follow.) Most students choose to hand-write their solutions on paper and then scan them to PDF using their phone; you should use a proper scanning app – we recommend Microsoft Office Lens or Adobe Scan – and not just submit photographs.

Tutorials

Tutorials are small groups of about a dozen students. You have been assigned to one of 38 tutorial groups, each with a member of staff as the tutor. Your tutorial group will meet five times, in Weeks 2, 4, 6, 8, and 10; you should check your timetable to see when and where your tutorial group meets.

The main goal of the tutorials will be to go over your answers to the non-assessed questions on the problems sheets in an interactive session. In this smaller group, you will be able to ask detailed questions of your tutor, and have the chance to discuss your answers to the problem sheet. Your tutor may ask you to present some of your work to your fellow students, or may give you the opportunity to work together with others during the tutorial. Your tutor may be willing to give you a hint on the assessed questions if you've made a first attempt but have got stuck. Because of the much smaller groups, the tutorials are the most valuable type of teaching on the module; you should make sure you attend, and you should be well prepared to ensure you make the most of the opportunity.

My recommended approach to problem sheets and tutorials is the following:

- Work through the problem sheet before the tutorial, spending plenty of time on it, and making multiple efforts at questions you get stuck on. I recommend spending *at least 4 hours per problem sheet*. This is a long time, but you shouldn't expect to be able to answer the hardest questions on a problem sheet with making multiple attempts. You don't have to wait until all lectures in a section are complete until starting to work on some of the questions – this is particularly important for students with Monday tutorials. Collaboration is encouraged when working through the non-assessed problems, but I recommend writing up your work on your own; answers to assessed questions must be solely your own work.
- Take advantage of the small group setting of the tutorial to ask for help or clarification on questions you weren't able to complete.
- After the tutorial, attempt again the questions you were previously stuck on.
- If you're still unable to complete a question after this second round of attempts, *then* consult the solutions.

Your tutor will also be the marker of your answers to the assessed questions on the problem sheets.

Attendance at tutorials is compulsory.

R worksheets

R is a programming language that is particularly good at working with probability and statistics. Learning to use R is an important part of this module, and is used in many other modules in the University, particularly in MATH1712 Probability and Statistics II. R is used by statisticians throughout academia and increasingly in industry too. Learning to program is a valuable skill for all students, and learning to use R is particularly valuable for students interested in statistics and related topics like actuarial science.

You will learn R by working through one R worksheet each week in your own time. Worksheets 3, 5, 7, 9 and 11 will also contain a few questions for assessment, which will be due by 2pm Monday the following week (except the last one). Each of these is worth 3% of your mark for a total of 15%. You will submit your answers through a Microsoft Form (details to follow later). I recommend spending one hour per week on the week's R worksheet, plus one extra hour if there are assessed questions that week.

Week	Worksheet	Deadline for assessed work
1	R basics	—
2	Vectors	—
3	Data in R	Monday 24 October (Week 4)
4	Plots I: Making plots	—
5	Plots II: Making plots better	Monday 7 November (Week 6)
6	RMarkdown (optional)	—
7	Discrete distributions	Monday 21 November (Week 8)
8	Discrete random variables	—

Week	Worksheet	Deadline for assessed work
9	Normal distribution	Monday 5 December (Week 10)
10	Law of large numbers	—
11	Recap	Thursday 15 December (Week 11)

You can read more about the language R, and about the program RStudio that we recommend you use to interact with R, in the R section of these notes.

To help you if you have problems with R, we have organised **optional R troubleshooting drop-in sessions**, where you can discuss any problems you have with an R expert, in Weeks 2 and 3. Check your timetable for details – these will be listed on your timetable as “practicals”.

Attendance at R troubleshooting drop-in sessions is optional.

Optional “office hours” drop-in sessions

If you there is something in the module you wish to discuss privately one-on-one with the module leader, the place for the is the optional weekly “office hours”, which will operate as drop-in sessions. These sessions are an optional opportunity for you to ask questions you have to a member of staff; these are particularly useful if there’s something on the module that you are stuck on or confused about, but I’m happy to discuss any statistics-related issues or questions you have.

I currently plan two optional “office hours” drop-in session per week:

- Thursdays from 1400 to 1500 in Roger Stevens LT 7
- Thursdays from 1600 to 1700 in Roger Stevens LT 17

Although only the second of these appears on your timetable, you are equally welcome at either. Depending on attendance levels, I may change arrangements as term continues. If neither time is possible, you may email me to book a time to talk to me.

Attendance at “office hours” drop-in sessions is optional. You should prioritise mandatory sessions (like lectures or tutorials, such as for LUBS1940 Economics for Management) over this optional session.

Time management

It is, of course, up to you how you choose to spend your time on this module. But my recommendations for your work would be something like this:

- **Lectures:** 2 hours per week, plus 1 hour per week reading through notes.
- **Problem sheets:** 4 hours per problem sheet, plus 1 extra hour for writing up and submitting answers to assessed questions.

- **R worksheets:** 1 hour per week, plus 1 extra hour if there are assessed questions.
- **Tutorials:** 1 hour every other week.
- **Revision:** 15 hours total at the end of the module.
- **Exam:** 2 hours.

That makes 100 hours in total. (MATH1710 is a 10-credit module, so is supposed to represent 100 hours work. MATH2700 students are expected to be able to use their greater experience to get through the material in just 75 hours, so should scale these recommendations accordingly.)

Exam

There will be an exam in January, which makes up the remaining 70% of your mark. The exam will consist of 20 short and 2 long questions, and will be time-limited to 2 hours. We'll talk more about the exam format near the end of the module.

Who should I ask about...?

There are over 420 students on this module. If each student emails me once a week, and if each email takes me 10 minutes to read and respond, that will take more than 14 hours of my time every day. Generally, it's much better to come to speak to me at the "office hours" drop-in session or, if it will be very quick, before or after a lecture.

- *I don't understand something in the notes or on a problem sheet:* Come to office hours, or ask your tutor in your next tutorial.
- *I'm having difficulties with R:* In Weeks 2 or 3, you should attend an R trouble-shooting drop-in session; at other times, come to office hours.
- *I have an admin question about arrangements for the module:* Come to office hours or talk to me before/after lectures.
- *I have an admin question about arrangements for my tutorial:* Contact your tutor.
- *I have an admin question about general arrangements for my programme as a whole:* Contact the Student Information Service or speak to your personal academic tutor.
- *I have a question about the marking of my assessed work on the problem sheets:* First, check your feedback on Gradescope; if you still have questions, contact your tutor.
- *I have a question about the marking of my assessed work on the R worksheets:* You can email me about this.
- *Due to truly exceptional and unforeseeable personal circumstances I require an extension on or exemption from assessed work:* You can apply by filling in the mitigating circumstances form at this link. Neither I nor your tutor can unilaterally offer an extension or exemption, so please don't ask. (Only exemptions, not extensions, are available for R worksheets.)

Content of MATH1710

Prerequisites

The formal prerequisite for MATH1710 is “Grade B in A-level Mathematics or equivalent”. I’ll assume you have some basic school-level maths knowledge, but I won’t assume you’ve studied probability or statistics in detail before (although I recognise that many of you will have). If you have studied probability and/or statistics at A-level (or post-16 equivalent) level, you’ll recognise some of the material in this module; however you should find that we go deeper in some areas, and that we treat the material through with a greater deal of mathematical formality and rigour. “Rigour” here means precisely stating our assumptions, and carefully *proving* how other statements follow from those assumptions.

Syllabus

The module has three parts: a short first part on “exploratory data analysis”, a long middle part on probability theory, and a short final part on a statistical framework called “Bayesian statistics”. There’s also the weekly R worksheets, which you could count as a fourth part running in parallel, but which will connect with the other parts too.

An outline plan of the topics covered is the following.

- **Exploratory data analysis** [2 lectures]: Summary statistics, data visualisation
- **Probability** [16 lectures]:
 - Probability with events: Probability spaces, probability axioms, examples and properties of probability, “classical probability” of equally likely events, independence, conditional probability, Bayes’ theorem [6 lectures]
 - Probability with random variables: Discrete random variables, expectation and variance, binomial distribution, geometric distribution, Poisson distribution, multiple random variables, law of large numbers, continuous random variables, exponential distribution, normal distribution, central limit theorem [10 lectures]
- **Bayesian statistics** [2 lectures]: Bayesian framework, Beta prior, normal–normal model
- Summary and revision [2 lectures]

You’ll notice that this module is heavier on the “Probability” than the “Statistics” of its title. MATH1712 Probability and Statistics II, on the other hand, which many students on this module will take next semester, is almost entirely “Statistics”.

Books

You can do well on this module by reading the notes and watching the videos, attending the lectures and tutorials, and working on the problem sheets and R worksheets, without needing to do any further reading beyond this. However, students can benefit from optional extra background reading or an alternative view on the material, especially in the parts of the module on probability. These books are also a good place to look if you want extra exercises and problems for revision.

For exploratory data analysis, you can stick to Wikipedia, but if you really want a book, I'd recommend:

- GM Clarke and D Cooke, *A Basic Course in Statistics*, 5th edition, Edward Arnold, 2004.

For the probability section, any book with a title like “Introduction to Probability” would do. Some of my favourites are:

- JK Blitzstein and J Hwang, *Introduction to Probability*, 2nd edition, CRC Press, 2019.
- G Grimmett and D Welsh, *Probability: An Introduction*, 2nd edition, Oxford University Press, 2014. (The library has online access.)
- SM Ross, *A First Course in Probability*, 10th edition, Pearson, 2020.
- RL Schaeffer and LJ Young, *Introduction to Probability and Its Applications*, 3rd edition, Cengage, 2010.
- D Stirzaker, *Elementary Probability*, 2nd edition, Cambridge University Press, 2003. (The library has online access.)

I also found lecture notes by Prof Oliver Johnson (University of Bristol) and Prof Richard Weber (University of Cambridge) to be useful.

On Bayesian statistics, we will only taste a brief introduction, but if you want a book, I recommend:

- JV Stone, *Bayes' Rule: A Tutorial Introduction to Bayesian Analysis*, Sebtel Press, 2013.

For R, there are many excellent resources online.

(For all these books I've listed the newest editions, but older editions are usually fine too.)

About these notes

These notes were written by Matthew Aldridge in 2021, and were edited and updated in 2022. They are based in part on previous notes by Dr Robert G Aykroyd and Prof Wally Gilks. Dr Jason Susanna Anquandah and Dr Aykroyd

advised on the R worksheets. Dr Aykroyd's help and advice on many aspects of the module was particularly valuable.

These notes (in the web format) should be accessible by screenreaders. If you have accessibility difficulties with these notes, contact me.

Part I: Exploratory data analysis

Chapter 1

Summary statistics

1.1 What is EDA?

Statistics is the study of data. **Exploratory data analysis** (or **EDA**, for short) is the part of statistics concerned with taking a “first look” at some data. Later, toward the end of this course, we will see more detailed and complex ways of building models for data, and in MATH1712 Probability and Statistics II (for those who take it) you will see many other statistical techniques – in particular, ways of testing formal hypotheses for data. But here we’re just interested in first impressions and brief summaries.

In this section, we will concentrate on two aspects of EDA:

- **Summary statistics:** That is, calculating numbers that briefly summarise the data. A summary statistic might tell us what “central” or “typical” values of the data are, how spread out the data is, or about the relationship between two different variables.
- **Data visualisation:** Drawing a picture based on the data is another way to show the shape (centrality and spread) of data, or the relationship between different variables.

Even before calculating summary statistics or drawing a plot, however, there are other questions it is important to ask about the data:

- *What is the data?* What variables have been measured? How were they measured? How many datapoints are there? What is the possible range of responses?
- *How was the data collected?* Was data collected on the whole population or just a smaller sample? If a sample: How was that sample chosen? Is that sample representative of the population?
- *Are there any outliers?* “Outliers” are datapoints that seem to be very different from the other datapoints – for example, are much larger or much smaller than the others. Each outlier should be investigated to seek

the reason for it. Perhaps it is a genuine-but-unusual datapoint (which is useful for understanding the extremes of the data), or perhaps there is an extraordinary explanation (a measurement or recording error, for example) meaning the data is not relevant. Once the reason for an outlier is understood, it then *might* be appropriate to exclude it from analysis (for example, the incorrectly recorded measurement). It's usually bad practice to exclude an outlier merely for being an outlier before understanding what caused it.

- *Ethical questions:* Was the data collected ethically and, where necessary, with the informed consent of the subjects? Has it been stored properly? Are their privacy issues with the collection and storage of the data? What ethical issues should be considered before publishing (or not publishing) results of the analysis? Should the data be kept confidential, or should it be openly shared with other researchers for the betterment of science?

1.2 What is R?

R is a programming language that is particularly good at working with probability and statistics. A convenient way to use the language R is through the program **RStudio**. An important part of this module is learning to use R, by completing weekly worksheets – you can read more in the R section of these notes.

R can easily and quickly perform all the calculations and draw all the plots in this section of notes on exploratory data analysis. In this text, we'll show the relevant R code. Code will appear like this:

```
data <- c(4, 7, 6, 7, 4, 5, 5)
mean(data)
```

```
## [1] 5.428571
```

Here, the code in the first shaded box is the R commands that are typed into RStudio, which you can type in next to the > arrow in the RStudio “console”. The numerical answers that R returns are shown here in the second unshaded box next to a double hashsign **##**. The **[1]** can be ignored (this is just R's way of saying that this is the first part of the answer – but the answer here only has one part anyway). Plots produced by R are displayed in these notes as pictures.

Most importantly for now, *you are not expected to understand the R code in this section yet*. The code is included so that, in the future, as you work through the R worksheets week by week, you can look back at the code in the section, and it will start to make sense. By the time you have finished R Worksheet 5 in week 5, you should be able understand most of the R code in this section.

1.3 Statistics of centrality

Suppose we have collected some data on a certain variable. We will assume here that we have n datapoints, each of which is a single real number. We can write this data as a vector

$$\mathbf{x} = (x_1, x_2, \dots, x_n).$$

A **statistic** is a calculation from the data \mathbf{x} , which is (usually) also a real number. In this section we will look at two types of “summary statistics”, which are statistics that we feel will give us useful information about the data.

We’ll look here at two types of summary statistic:

- **Statistics of centrality**, which tell us where the “middle” of the data is.
- **Statistics of spread**, which tell us how far the data typically spreads out from that middle.

Some measures of centrality are the following.

Definition 1.1. Consider some real-valued data $\mathbf{x} = (x_1, x_2, \dots, x_n)$.

- The **mode** is the most common value of x_i . (If there are multiple joint-most common values, they are all modes.)
- Suppose the data is ordered as $x_1 \leq x_2 \leq \dots \leq x_n$. Then the **median** is the central value in the ordered list. If n is odd, this is $x_{(n+1)/2}$; if n is even, we normally take halfway between the two central points, $\frac{1}{2}(x_{n/2} + x_{n/2+1})$.
- The **mean** \bar{x} is

$$\bar{x} = \frac{1}{n}(x_1 + x_2 + \dots + x_n) = \frac{1}{n} \sum_{i=1}^n x_i.$$

(In that last expression, we’ve made use of Sigma notation to write down the sum.)

Example 1.1. Some packets of Skittles (a small fruit-flavoured sweet) were opened, and the number of Skittles in each packet counted. There were 13 packets, and the number of sweets (sorted from smallest to largest) were:

59, 59, 59, 59, 60, 60, 60, 61, 62, 62, 62, 63, 63.

The mode is 59, because there were 4 packets containing 59 sweets; more than any other number. Since there are $n = 13$ packets, the middle packet is number $i = 7$, so the median is $x_7 = 60$. The mean is

$$\bar{x} = \frac{1}{13}(59 + 59 + \dots + 63) = \frac{789}{13} = 60.7.$$

The median is one example of a “quantile” of the data. Suppose our data is increasing order again. For $0 \leq \alpha \leq 1$, the α -**quantile** $q(\alpha)$ of the data is the datapoint α of the way along the list. Generally, $q(\alpha)$ is equal to $x_{1+\alpha(n-1)}$ when $1 + \alpha(n-1)$ is an integer. (If $1 + \alpha(n-1)$ isn’t an integer, there are various conventions of how to choose that we won’t go into here. R has *nine* different settings for choosing quantiles! – we will always just use R’s default choice.)

- The **median** is the $\frac{1}{2}$ -quantile $q(\frac{1}{2})$, which is $q(\frac{1}{2}) = x_7 = 60$ for this data.
- The **minimum** is the 0-quantile $q(0)$, which is $q(0) = x_1 = 59$ for this data.
- The **maximum** is the 1-quantile $q(1)$, which is $q(1) = x_{13} = 63$ for this data.
- The **lower quartile** (that's “quartile”, as in “quarter” – not “quantile”) is the $\frac{1}{4}$ -quantile $q(\frac{1}{4})$, which is $q(\frac{1}{4}) = x_4 = 59$ for this data.
- The **upper quartile** is the $\frac{3}{4}$ -quantile $q(\frac{3}{4})$, which is $q(\frac{3}{4}) = x_{10} = 62$ for this data.

The following R code reads in some data which has the daily average temperature in Leeds in 2020, divided into months. We can find, for example, the mean October temperature or the lower quartile of the July temperature.

```
temperature <- read.csv("https://mpaldridge.github.io/math1710/data/temperature.csv")
jul <- temperature[temperature$month == "jul", ]
oct <- temperature[temperature$month == "oct", ]

mean(oct$temp)
```

```
## [1] 11.93548
```

```
quantile(jul$temp, probs = 1 / 4)
```

```
## 25%
```

```
## 15
```

1.4 Statistics of spread

Some measures of spread are:

Definition 1.2. The **number of distinct observations** is precisely that: the number of different datapoints we have after removing any repeats.

The **interquartile range** is the difference between the upper and lower quartiles $\text{IQR} = q(\frac{3}{4}) - q(\frac{1}{4})$.

The **sample variance** is

$$s_x^2 = \frac{1}{n-1} ((x_1 - \bar{x})^2 + \dots + (x_n - \bar{x})^2) = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2,$$

where \bar{x} is the sample mean from before. The **standard deviation** $s_x = \sqrt{s_x^2}$ is the square-root of the sample variance.

The formula we've given for sample variance is sometimes called the “definitional formula”, as it's the formula used to *define* the sample variance. We can

rearrange that formula as follows:

$$\begin{aligned}
 s_x^2 &= \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \\
 &= \frac{1}{n-1} \sum_{i=1}^n (x_i^2 - 2x_i\bar{x} + \bar{x}^2) \\
 &= \frac{1}{n-1} \left(\sum_{i=1}^n x_i^2 - \sum_{i=1}^n 2x_i\bar{x} + \sum_{i=1}^n \bar{x}^2 \right) \\
 &= \frac{1}{n-1} \left(\sum_{i=1}^n x_i^2 - 2\bar{x} \sum_{i=1}^n x_i + \bar{x}^2 \sum_{i=1}^n 1 \right) \\
 &= \frac{1}{n-1} \left(\sum_{i=1}^n x_i^2 - 2n\bar{x}^2 + n\bar{x}^2 \right) \\
 &= \frac{1}{n-1} \left(\sum_{i=1}^n x_i^2 - n\bar{x}^2 \right).
 \end{aligned}$$

Here, the first line is the definitional formula; the second line is from expanding out the bracket; the third line is taking the sum term-by-term; the fourth line takes any constants (things not involving i) outside the sums; the fifth line uses $\sum_{i=1}^n x_i = n\bar{x}$, from the definition of the mean, and $\sum_{i=1}^n 1 = 1 + 1 + \dots + 1 = n$; and the sixth line simplifies the final two terms.

This has left us with

$$s_x^2 = \frac{1}{n-1} \left(\sum_{i=1}^n x_i^2 - n\bar{x}^2 \right).$$

This is sometimes called the “computational formula”; this is because it usually takes fewer presses of calculator buttons to compute the sample variance with this formula rather than the definitional formula. (But make sure you keep enough decimal points in \bar{x}^2 .)

Going back to our weather data in R, we can find the sample variance of the October weather or the interquartile range of the July weather.

```
var(oct$temp)
```

```
## [1] 2.862366
```

```
IQR(jul$temp)
```

```
## [1] 3
```

Summary

- Exploratory data analysis is about taking a first look at data.

- Summary statistics are numbers calculated from data that give us useful information about the data.
- Summary statistics that measure the centre of the data include the mode, median, and mean.
- Summary statistics that measure the spread of the data include the number of distinct outcomes, the interquartile range, and the sample variance.

Chapter 2

Data visualisations

Data visualisations – drawings or graphs based on data – can help us to understand the “shape” of a dataset as part of exploratory data analysis. In this lecture, we’ll look at three types of data visualisation.

2.1 Boxplots

A **boxplot** is a useful way to illustrate numerical data. It can be easier to tell the difference between different data sets “by eye” when looking at a boxplot, rather than examining raw summary statistics.

A boxplot is drawn as follows:

- The vertical axis represents the data values.
- Draw a box from the lower quartile $q(\frac{1}{4})$ to the median $q(\frac{1}{2})$.
- Draw another box on top of this from the median $q(\frac{1}{2})$ to the upper quartile $q(\frac{3}{4})$. Note that size of these two boxes put together is the interquartile range.
- Decide which datapoints are outliers, and plot these with circles. (The R default is that any data point less than $q(\frac{1}{4}) - 1.5 \times \text{IQR}$ or greater than $q(\frac{3}{4}) + 1.5 \times \text{IQR}$ is an outlier.)
- Out from the two previous boxes, draw “whiskers” to the minimum and maximum non-outlier datapoints.

When we have multiple datasets, drawing boxplots next to each other can help us to compare the datasets. Here are two boxplots from the July and October temperature data we used in the last lecture. What do you conclude about the data from these boxplots?

```
boxplot(jul$temp, oct$temp,
        names = c("July", "October"),
        ylab = "Daily maximum temperature (degrees C) in Leeds"
)
```

(And yes, I did check the outlier to make sure it was a genuine datapoint.)

2.2 Histograms

Often when collecting data, we don't collect exact data, but rather collect data clumped into "bins". For example, suppose a student wished to use a questionnaire to collect data on how long it takes people to reach campus from home; they might not ask "Exactly how long does it take?", but rather give a choice of tick boxes: "0–5 minutes", "5–10 minutes", and so on.

Consider the following binned data, from $n = 100$ students:

Time	Frequency	Relative frequency
0–5 minutes	4	0.04
5–10 minutes	8	0.08
10–15 minutes	21	0.21
15–30 minutes	42	0.42
30–45 minutes	15	0.15
45–60 minutes	8	0.08
60–120 minutes	2	0.02

Time	Frequency	Relative frequency
Total	100	1

Here the **frequency** f_j of bin j is simply the number of observations in that bin; so, for example, 42 students had journey lengths of between 15 and 30 minutes. The **relative frequency** of bin j is f_j/n ; that is, the proportion of the observations in that bin.

Which bin would you say is the most popular – that is, the “modal” bin? The bin with the most observations in it is the “15–30 minute” bin. But this bin covers 15 minutes, while some of the other bins only cover 5 minutes. It would be a fairer comparison to look at the **frequency density**: the relative frequency divided by the size of the bin.

Time	Frequency	Relative frequency	Frequency density
0–5 minutes	4	0.04	0.008
5–10 minutes	8	0.08	0.016
10–15 minutes	21	0.21	0.042
15–30 minutes	42	0.42	0.028
30–45 minutes	15	0.15	0.010
45–60 minutes	8	0.08	0.005
60–120 minutes	2	0.02	0.0003
Total	100	1	

In the first row, for example, the relative frequency is 0.04 and the size of the bin is 5 minutes, so the frequency density is $0.04/5 = 0.008$. We now see that the modal bin – the bin with the highest frequency *density* – is in fact the “10–15 minutes” bin. This bin has somewhat fewer datapoints than the “15–30 minutes” bin, but they’re squashed into a much smaller bin.

Data in bins can be illustrated with a **histogram**. A histogram has the measurement on the x-axis, with one bar across the width of each bin, where bars are drawn up to the height of the corresponding frequency density. Note that this means that the area of the bar is exactly the relative frequency of the corresponding bin.

If all the bins are the same width, frequency density is directly proportional to frequency and to relative frequency, so it can be clearer use one of those as the y-axis instead in the equal-width-bins case.

Here is a histogram for our journey-time data:

```
journeys <- read.csv("https://mpaldrige.github.io/math1710/data/journeys.csv")
bins <- c(0, 5, 10, 15, 30, 45, 60, 120)

hist(journeys$midpoint, breaks = bins,
      xlab = "Journey length (min)", ylab = "frequency density", main = ""
)
```

Often we draw histograms because the data was collected in bins in the first place. But even when we have exact data, we might *choose* to divide it into bins for the purposes of drawing a histogram. In this case we have to decide where to put the “breaks” between the bins. Too many breaks too close together, and the small number of observations in each bin will give “noisy” results (see left); too few breaks too far apart, and the wide bins will mean we lose detail (see right).

```
set.seed(2172)
hist_data <- c(rnorm(30, 8, 2), rnorm(40, 12, 3)) # Some fake data

hist(hist_data, breaks = 40, main = "Too many bins")
hist(hist_data, breaks = 2, main = "Too few bins")
```

We can also calculate some summary statistics even when we have binned data. We mentioned the mode earlier, where the modal bin is the bin of highest frequency density.

What is the median journey length? Well, we don't know exactly, but $0.04 + 0.08 + 0.21$ (the first three bins) is less than 0.5, while $0.04 + 0.08 + 0.21 + 0.42$ (including the fourth bin) is greater than 0.5. So we know that the median student is in the fourth bin, the "15–30 minute" bin, and we can say that the median journey length is between 15 and 30 minutes.

Since we don't have the exact data, it's not possible to exactly calculate the mean and variance. However, we can often get a good estimate by assuming that each observation was in fact right in the centre of its bin. So, for example, we could assume that all 4 observations in the "0–5 minutes" bin were journeys of exactly 2.5 minutes. Of course, this isn't true (or is highly unlikely to be true), but we can often get a good approximation this way.

For our journey-time data, our approximation of the mean would be

$$\bar{x} = \frac{1}{100}(4 \times 2.5 + 8 \times 7.5 + \dots + 2 \times 90) = 24.4.$$

More generally, if m_j is the midpoint of bin j and f_j its frequency, then we can calculate the binned mean and binned variance by

$$\begin{aligned}\bar{x} &= \frac{1}{n} \sum_j f_j m_j \\ s_x^2 &= \frac{1}{n-1} \sum_j f_j (m_j - \bar{x})^2\end{aligned}$$

2.3 Scatterplots

Often, more than one piece of data is collected from each subject, and we wish to compare that data, to see if there is a relationship between the variables.

For example, we could take n second-year maths students, and for each student i , collect their mark x_i in MATH1710 and their mark y_i in MATH1712. This gives us two "paired" datasets, $\mathbf{x} = (x_1, x_2, \dots, x_n)$ and $\mathbf{y} = (y_1, y_2, \dots, y_n)$. We can calculate sample statistics of draw plots for \mathbf{x} and for \mathbf{y} individually. But we might also want to see if there is a relationship *between* \mathbf{x} and \mathbf{y} : Do students with high marks in MATH1710 also get high marks in MATH1712?

A good way to visualise the relationship between two variables is to use a **scatterplot**. In a scatterplot, the i th data pair (x_i, y_i) is illustrated with a mark (such as a circle or cross) whose x-coordinate has the value x_i and whose y-coordinate has the value y_i .

In the following scatterplot, we have $n = 50$ datapoints for the 50 US states; for each state i , x_i is the Republican share of the vote in that state in the 2016 Trump–Clinton presidential election, and y_i is the Republican share of the vote in that state in the 2020 Trump–Biden election.

```
elections <- read.csv("https://mpaldrige.github.io/math1710/data/elections.csv")

plot(elections$X2016, elections$X2020,
     col = "blue",
     xlab = "Republican share of the two-party vote, 2016 (%)",
     ylab = "Republican share of the two-party vote, 2020 (%)")

abline(h = 50, col = "grey")
abline(v = 50, col = "grey")
abline(0.195, 0.963, col = "red")
```

We see that there is a strong relationship between \mathbf{x} and \mathbf{y} , with high values of x corresponding to high values of y and vice versa. Further, the points on the scatterplot lie very close to a straight line.

A useful summary statistic here is the **correlation**

$$r_{xy} = \frac{s_{xy}}{s_x s_y},$$

where s_{xy} is the **sample covariance**

$$s_{xy} = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}),$$

and $s_x = \sqrt{s_x^2}$ and $s_y = \sqrt{s_y^2}$ are the standard deviations.

The correlation r_{xy} is always between -1 and $+1$. Values of r_{xy} near $+1$ indicate that the scatterpoints are close to a straight line with an upward slope (big x = big y); values of r_{xy} near -1 indicate that the scatterpoints are close to a

straight line with a downward slope (big x = small y); and values of r_{xy} near 0 indicate that there is a weak linear relationship between x and y .

For the elections data, the correlation is

```
cor(elections$X2016, elections$X2020)
```

```
## [1] 0.9919659
```

which, as we expected, is extremely high.

Summary

- Boxplots show the shape of numerical data, and can compare different datasets.
- Histograms show the shape of binned data.
- Scatterplots show the relationship between two datasets.

Problem Sheet 1

You can download this problem sheet as a PDF file

This is Problem Sheet 1, which covers material from Lectures 1 and 2 of the notes. You should work through all the questions on this problem sheet in preparation for your tutorial in Week 2. Questions C1 and C2 are assessed questions, and are due in by **2pm on Monday 17 October**. I recommend spending about 4 hours on this problem sheet, plus 1 extra hour to neatly write up and submit your answers to the assessed questions.

A: Short questions

The first three questions are **short questions**, which are intended to be mostly not too difficult. Short questions usually follow directly from the material in the lectures. Here, you should clearly state your final answer, and give enough working-out (or a short written explanation) for it to be clear how you reached that answer. You can check your answers with the solutions-without-working at the bottom of this sheet; solutions-with-working will be available later. If you get stuck on any of these questions, you might want to ask for guidance in your tutorial.

A1. Consider again the “number of Skittles in each packet” data from Example 1.1.

59, 59, 59, 59, 60, 60, 60, 61, 62, 62, 62, 63, 63.

- (a) Calculate the mean number of Skittles in each packet.
- (b) Calculate the sample variance using the computational formula.
- (c) Calculate the sample variance using the definitional formula.
- (d) Out of (b) and (c), which calculation did you find easier, and why?

A2. Consider the following data sets of the age of elected politicians on a local council. (The “18–30” bin, for example, means from one’s 18th birthday to the moment before one’s 30th birthday, so lasts 12 years.)

Age (years)	Frequency	Relative frequency	Frequency density
18–30	1		

Age (years)	Frequency	Relative frequency	Frequency density
30–40	3		
40–45	4		
45–50	5		
50–55	3		
55–60	1		
60–70	3		
Total	20	1	—

(a) Complete the table by filling in the relative frequency and frequency densities.

(b) What is the median age bin?

(c) What is the modal age bin?

(d) Calculate (the standard approximation of) the mean age of the politicians.

A3. Consider the two datasets illustrated by the boxplots below. Write down some differences between the two datasets.

B: Long questions

The next four questions are **long questions**, which are intended to be harder. Long questions often require you to think originally for yourself, not just directly follow procedures from the notes. You may not be able to solve all of these questions, although you should make multiple attempts to do so. Here, your answers should be written in complete sentences, and you should carefully explain in words each step of your working. Your answers to these questions – not only their mathematical content, but also how to clearly write good solutions – are likely to be the main topic for discussion in your tutorial.

B1. For each of the two datasets below, calculate the following summary statistics, or explain why it is not possible to do so: mode; median; mean; number of distinct outcomes; inter-quartile range; and sample variance.

(a) Six packets of Skittles are opened together, and the total number of sweets of each colour is:

Colour	Red	Orange	Yellow	Green	Purple
Number of Skittles	67	71	87	74	62

(b) Shirt sizes for a university football squad:

Colour	Xtra Small	Small	Medium	Large	Xtra Large
Number of shirts	0	1	6	4	5

B2. A summary statistic is informally said to be “robust” if it typically doesn’t change much if a small number of outliers are introduced to a large dataset, or “sensitive” if it often changes a lot when a small number of outliers are introduced. Briefly discuss the robustness or sensitivity of the following summary statistics: (a) mode; (b) median; (c) mean; (d) number of distinct outcomes; (e) inter-quartile range; and (f) sample variance.

B3. Let $\mathbf{a} = (a_1, a_2, \dots, a_n)$ and $\mathbf{b} = (b_1, b_2, \dots, b_n)$ be two real-valued vectors of the same length. Then the *Cauchy–Schwarz inequality* says that

$$\left(\sum_{i=1}^n a_i b_i \right)^2 \leq \left(\sum_{i=1}^n a_i^2 \right) \left(\sum_{i=1}^n b_i^2 \right).$$

(a) By making a clever choice of (a_i) and (b_i) in the Cauchy–Schwarz inequality, show that $s_{xy}^2 \leq s_x^2 s_y^2$.

(b) Hence, show that the correlation r_{xy} satisfies $-1 \leq r_{xy} \leq 1$.

B4. A researcher wishes to study the effect of mental health on academic achievement. The researcher will collect data on the mental health of a cohort of students by asking them to fill in a questionnaire, and will measure academic

achievement via the students' scores on their university exams. Discuss some of the ethical issues associated with the collection, storage, and analysis of this data, and with the publication of the results of the analysis. Are there ways to mitigate these issues?

(It's not necessary to write an essay for this question – a few short bulletpoints will suffice. There may be an opportunity to discuss these issues in more detail in your tutorial.)

C: Assessed questions

The last two questions are **assessed questions**. This means you will submit your answers, and your answers will be marked by your tutor. These two questions count for 3% of your final mark for this module. If you get stuck, your tutor may be willing to give you a small hint in your tutorial.

The deadline for submitting your solutions is **2pm on Monday 17 October** at the beginning of Week 3. Submission will be via Gradescope, which you can access via Minerva. You should submit your answers as a single PDF file. Most students choose to hand-write their work, then scan it to PDF using their phone; if you do this, you should use a proper scanning app (like Microsoft Lens or Adobe Scan) – please do not just submit photographs. Your work will be marked by your tutor and returned on Monday 24 October, when solutions will also be made available.

Question C1 is a “short question”, where brief explanations or working are sufficient; Question C2 is a “long question”, where the marks are not only for mathematical accuracy but also for the clarity and completeness of your explanations.

You should not collaborate with others on the assessed questions: your answers must represent solely your own work. The University's rules on academic integrity – and the related punishments for violating them – apply to your work on the assessed questions.

C1. The monthly average exchange rate for US dollars into British pounds over a 12-month period was:

1.306, 1.301, 1.290, 1.266, 1.268, 1.302,
1.317, 1.304, 1.284, 1.268, 1.247, 1.215.

- (a) Calculate the median for this data.
- (b) Calculate the mean for this data.
- (c) Calculate the sample variance for this data.
- (d) Is the mode an appropriate summary statistic for this sort of data? Why/why not?

C2. (a) Prove the following computational formula for the sample covariance:

$$s_{xy} = \frac{1}{n-1} \left(\sum_{i=1}^n x_i y_i - n \bar{x} \bar{y} \right).$$

(b) Suppose that a dataset $\mathbf{x} = (x_1, x_2, \dots, x_n)$ (with $n \geq 2$) has sample variance $s_x^2 = 0$. Show that all the datapoints are in fact equal.

Solutions to short questions

A1. (a) 60.7, (b) 2.40, (c) 2.40, (d) —. **A2.** (a) —, (b) 45–50, (c) 45–50, (c) 47.3. **A3.** —

Part II: Probability

Chapter 3

Sample spaces and events

3.1 What is probability?

We now begin the big central block of this module, on probability theory.

Probability theory is the study of randomness. Probability, as an area of mathematics, is a fascinating subject in its own right. However, probability is particularly important due to its usefulness in applications – especially in statistics (the study of data), in finance, and in actuarial science (the study of insurance).

Probability is well suited to modelling situations that involve randomness, uncertainty, or unpredictability. If we you want to predict the time of the next solar eclipse, a deterministic (that is, non-random) model based on physical laws will tell you when the sun, the moon, and the earth will be in the correct positions; but if you want to predict the weather tomorrow, or the price of a share of Apple stock next month, or the results of an election next year, you will need a probabilistic model that takes into account the uncertainty in the outcome. A probabilistic model could tell you the most likely outcome, or a range of the most probable outcomes.

So what do we mean when we talk about the “probability” of an event occurring? You might say that the probability of an event is a measure of “how likely” it is to occur, or what the “chance” of it occurring is.

More concretely, here are some interpretations of probability:

- **Subjective (or Bayesian) probability:** The probability of an event is the way someone expresses their degree of belief that the event will occur, based on their own judgement, and given the evidence they have seen. Their belief is measured on a scale from 0 to 1, from probabilities near 0 meaning they believe the event is very unlikely to occur to probabilities near 1 meaning they believe the event is very likely to occur.
 - This interpretation is philosophically sound, but a bit vague to be the basis for a mathematics module.

- **Classical (or enumerative) probability:** Suppose there are a finite number of equally likely outcomes. Then the probability of an event is the proportion of those outcomes that correspond to the event occurring. So when we say that a randomly dealt card has a probability $\frac{1}{13}$ of being an ace, this is because there are 52 cards of which 4 are aces, so the proportion of favourable outcomes is $\frac{4}{52} = \frac{1}{13}$.
 - This interpretation is good for simple procedures like flipping a fair coin, rolling a dice, or dealing cards, where the “finite number of equally likely outcomes” assumption holds. But we want to be able to study more complicated situations, where some outcomes are more likely than others, or where infinitely many different outcomes are possible.
- **Frequentist probability:** In a repeated experiment, the probability of an event is its long-run frequency. That is, if we repeat an experiment a very large number of times, the probability of the event is (approximately) the proportion of the experiments in which the event occurs. So when we say a biased coin has probability 0.9 of landing heads, we mean that were we toss it 1000 times, we would expect to see very close to $0.9 \times 1000 = 900$ heads.
 - There are two problems with this. First, this doesn’t deal with events that can’t be repeated over and over again (like “What’s the probability that England win the 2022 World Cup?”). Second, to answer the question, “Yes, but *how* close to the probability should the proportion of occurrences be?”, you end up having to answer, “Well, it depends on the probability,” and you’ve got a circular definition.
- **Mathematical probability:** We have a function that assigns to each event a number between 0 and 1, called its probability, and that function has to obey certain mathematical rules, called “axioms”.

It will not surprise you to learn that, in this mathematics course, we will take the “mathematical probability” approach. However, we will also learn useful things about the other approaches: we will see that classical probability is one special case of mathematical probability; we will see a result called the “law of large numbers” that says that the long-run frequency does indeed get closer and closer to the mathematical probability; and a result called “Bayes’ theorem” will advise a subjectivist on how to update her subjective beliefs when she sees new evidence.

3.2 Sample spaces and events

Taking the “mathematical probability” approach, we will want to give a formal mathematical definition of the *probability* of an event. But even before that, we need to give a formal mathematical definition of an *event* itself. Our setup will be this:

- There is a set called the **sample space**, normally given the letter Ω (upper-case Omega), which is the set of all possible outcomes.

- An element of the sample space Ω is a **sample outcome**, sometimes given the letter ω (lower-case omega), represents one of the possible outcomes.
- An **event** is a set of sample outcomes; that is, a subset of the sample space Ω . Events are often given letters like A, B, C . We write $A \subset \Omega$ to mean that A is an event in (or, equivalently, is a subset of) the sample space Ω .

This will be easier to understand with some concrete examples. We write a set (such as a sample space or an event) by writing all the elements of that set inside curly brackets $\{ \}$, separated by commas.

Example 3.1. Suppose we toss a (possibly biased) coin, and record whether it lands heads or tails. Then our sample space is $\Omega = \{H, T\}$, where the sample outcome H denotes heads and the sample outcome T denotes tails.

The event that the coin lands heads is $\{H\}$.

Example 3.2. Suppose we roll a dice, and record the number rolled. Then our sample space is $\Omega = \{1, 2, 3, 4, 5, 6\}$, where the sample outcome 1 corresponds to rolling a one, and so on.

The event “we roll an even number” is $\{2, 4, 6\}$. The event “we roll at least a five” is $\{5, 6\}$.

Example 3.3. Suppose we wish to count how many claims are made to an insurance company in a year. We could model this by taking the sample space Ω to be $\mathbb{Z}_+ = \{0, 1, 2, \dots\}$, the set of all non-negative integers.

The event “the company receives less than 1000 claims” is $\{0, 1, 2, \dots, 998, 999\}$.

Example 3.4. Suppose we want a computer to pick a random number between 0 and 1. We could model this by taking the sample space Ω to be the interval $[0, 1]$ of all real numbers between 0 and 1.

The event “the number is bigger than $\frac{1}{2}$ ” is the sub-interval $(\frac{1}{2}, 1]$ of all real numbers greater than $\frac{1}{2}$ but no bigger than 1. The event “the first digit is a 7” is the sub-interval $[0.7, 0.8)$. The event “the random number is exactly $1/\sqrt{2}$ ” is $\{1/\sqrt{2}\}$.

In the first two examples, the sample space Ω was finite. In third example, the sample space was infinite but “countably infinite”, in that it could be counted using the discrete values of the positive integers. Both of these were for *counting* discrete observations. In the fourth example, the sample space was infinite but “uncountably infinite”, in that it had a sliding scale or “continuum” of gradually varying measurements. This was for *measuring* continuous observations. This distinction will be important later in the course.

For any sample space Ω , there are two special events that always exist. There’s Ω itself, the event containing all of the sample outcomes, which represents “something happens”. There’s also the empty set \emptyset , which contains none of the sample outcomes, which represents “nothing happens”. Common sense suggests that Ω should have probability 1, because *something* is bound to happen – this will later be one of our probability “axioms”. Common sense also suggests that \emptyset

should have probability 0, because it can't be that *nothing* happens – this will not be one probability axioms, but we'll show that it follows logically from the axioms we do choose.

3.3 Set theory

Since we've now defined events as being sets – specifically, subsets of the sample space Ω – it will be useful to mention a little set basic theory here.

First, there are ways we can build new sets (or events) out of old. It's fine to just read the words and look at the pictures for these definitions, but those who want to read the equations too will need to know this:

- $\omega \in A$ means “ ω is in A ” or “ ω is an element of A ”, while $\omega \notin A$ means the opposite, that ω is *not* in A ;
- a colon $:$ in the middle of set notation should be read as “such that”;
- so $\{\omega \in \Omega : \text{fact about } \omega\}$ should be read as “the set of sample points ω in the sample space Ω such that the fact is true”.

Definition 3.1. Consider a sample space Ω , and let A and B be events in that sample space.

- **NOT:** The **complement** of A , written A^c (and said “ A complement” or “not A ”), is the set of sample points not in A ; that is

$$A^c = \{\omega \in \Omega : \omega \notin A\}.$$

This represents the event that A does not occur.

- **AND:** The **intersection** of A and B , written $A \cap B$ (and said “ A intersect B ” or “ A and B ”) is the set of sample points in both A and B ; that is,

$$A \cap B = \{\omega \in \Omega : \omega \in A \text{ and } \omega \in B\}.$$

This represents the event that both A and B occur.

- **OR:** The **union** of A and B , written $A \cup B$ (and said “ A union B ” or “ A or B ”) is the set of sample points in A or in B ; that is,

$$A \cup B = \{\omega \in \Omega : \omega \in A \text{ or } \omega \in B\}.$$

This represents the event that A occurs or B occurs. (In mathematics, “or” includes “both”, so a sample outcome in both A and B is in $A \cup B$ too.)

Example 3.5. Suppose we are rolling a dice, so our sample space is $\Omega = \{1, 2, 3, 4, 5, 6\}$. Let $A = \{2, 4, 6\}$ be the event that we roll an even number, and let $B = \{5, 6\}$ be the event that we roll at least a 5. Then

$$\begin{aligned} A^c &= \{1, 3, 5\} = \{\text{roll an odd number}\}, \\ A \cap B &= \{6\} = \{\text{roll a 6}\}, \\ A \cup B &= \{2, 4, 5, 6\}. \end{aligned}$$

An important case is when two events A, B cannot happen at the same time; that is, $A \cap B = \emptyset$ (“ A intersect B is the empty set”). In this case, we say that A and B are **disjoint** or **mutually exclusive**. For example, when Ω is a deck of cards, then $A = \{\text{the card is a spade}\}$ and $B = \{\text{the card is red}\}$ are disjoint, because a card cannot be both a spade (a black suit) and red.

You might think that if two events are disjoint, then it would be reasonable to find the probability of their union – that is, the probability that one (and, by necessity, only one) of them happens – you can just add the two separate probabilities together. This will be another of our “axioms” of probability.

There are a few rules about ways you can combine the complement, intersection and union operations. These are ways of building new events from old.

- The **double complement law** tells us that not-not- A is the same as A :

$$(A^c)^c = A.$$

This says that if it’s not “not-raining”, then it’s raining!

- The **distributive laws** tell us we can “multiply out of the brackets” with sets:

$$\begin{aligned} A \cap (B \cup C) &= (A \cap B) \cup (A \cap C), \\ A \cup (B \cap C) &= (A \cup B) \cap (A \cup C). \end{aligned}$$

The first says that if you are eating a burger with fries or salad, then you're eating a burger with fries or eating a burger with salad. The second is a bit less intuitive, I find, but it's clear that if A is true then the first of each of the terms on the right is true, while if both B and C are true then the second of each of the terms on the right is true.

- **De Morgan's laws** tell us how complements interact with intersection/unions:

$$(A \cap B)^c = A^c \cup B^c$$

$$(A \cup B)^c = A^c \cap B^c$$

The first of these says that if it's not a Monday in October, then either it's not Monday or it's not October (or both). The second says that if a maths lecture is not "useful or fun", then it's not useful and it's not fun. (Augustus De Morgan was a British mathematician of the 19th century who did important work in logic.)

For this module, these mostly count as "common sense" – but if you ever do need to prove one of these statements (or a similar one), one way is to use a Venn diagram.

Let's prove the second distributive law,

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C),$$

with a Venn diagram as an example.

We can build the left-hand side of the law as:

The left-hand figure is A , the middle figure is $B \cap C$, and the right-hand figure is union of these, $A \cup (B \cap C)$.

Then for the right-hand side of the law, we have:

The left-hand figure is $A \cup B$, the middle figure is $A \cup C$, and the right-hand figure is intersection of these, $(A \cup B) \cap (A \cup C)$.

We see that the areas shaded in two right-hand figures are the same, so it is indeed the case that $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$.

Summary

- A sample space Ω is a set representing all possible sample outcomes.
- An event is a subset of Ω .
- For events A and B , we also have the complement “not A ” A^c , the intersection “ A and B ” $A \cap B$, and the union “ A or B ” $A \cup B$.

Chapter 4

Probability

4.1 Probability axioms

Recall that, in this mathematics course, the probability of an event will be a real number that satisfies certain properties, which we call **axioms**.

Definition 4.1. Let Ω be a sample space. A **probability measure** on Ω is a function \mathbb{P} that assigns to each event $A \subset \Omega$ a real number $\mathbb{P}(A)$, called the **probability** of A , and that satisfies the following three axioms:

1. $\mathbb{P}(A) \geq 0$ for all events $A \subset \Omega$;
2. $\mathbb{P}(\Omega) = 1$;
3. if A_1, A_2, \dots is a finite or infinite sequence of disjoint events, then

$$\mathbb{P}(A_1 \cup A_2 \cup \dots) = \mathbb{P}(A_1) + \mathbb{P}(A_2) + \dots.$$

The sample space Ω together with the probability measure \mathbb{P} are called a **probability space**.

Axiom 1 says that all probabilities are non-negative numbers. Axiom 2 says the probability that *something* happens is 1. Axiom 3 says that *for disjoint events* the probability that one of them happens is the sum of the individual probabilities. (Those who like their mathematical statements very precise should note that an infinite sequence in Axiom 3 must be “countable”; that is, indexed by the natural numbers 1, 2, 3,)

These axioms of probability (and our later results that follow from them) were first written down by the Russian mathematician Andrey Nikolaevich Kolmogorov in 1933. This marked the point from when probability theory could now be considered a proper branch of mathematics – just as legitimate as geometry or number theory – and not just a past-time that can be useful to help gamblers calculate their odds. I always find it surprising that the axioms of probability are less than 90 years old!

There are other properties that it seems natural that a probability measure should have aside from the axioms – for example, that $\mathbb{P}(A) \leq 1$ for all events A . But we will show shortly that other properties can be proven just by starting from the three axioms.

But first, let's see some examples.

Example 4.1. Suppose we wish to model tossing an biased coin the is heads with probability p , where $0 \leq p \leq 1$.

Our probability space is $\Omega = \{H, T\}$. The probability measure is given by

$$\begin{aligned}\mathbb{P}(\emptyset) &= 0 & \mathbb{P}(\{H\}) &= p \\ \mathbb{P}(\{T\}) &= 1 - p & \mathbb{P}(\{H, T\}) &= 1.\end{aligned}$$

Let's check that the axioms hold:

1. Since $0 \leq p \leq 1$, all the probabilities are greater than or equal to 0.
2. It is indeed the case that $\mathbb{P}(\Omega) = \mathbb{P}(\{H, T\}) = 1$.
3. The only nontrivial disjoint union to check is $\{H\} \cup \{T\} = \{H, T\}$, where we see that

$$\mathbb{P}(\{H\}) + \mathbb{P}(\{T\}) = p + (1 - p) = 1 = \mathbb{P}(\{H, T\}),$$

as required.

Example 4.2. Suppose we wish to model rolling a dice.

Our sample space is $\{1, 2, 3, 4, 5, 6\}$. The probability measure is given by

$$\mathbb{P}(A) = \frac{|A|}{6},$$

where $|A|$ is the number of sample outcomes in A .

So, for example, the probability of rolling an even number is

$$\mathbb{P}(\{2, 4, 6\}) = \frac{3}{6} = \frac{1}{2}.$$

The dice rolling is a particular case of the “classical probability” of equally likely outcomes. We'll look at this more in the next lecture, and prove that the classical probability measure does indeed satisfy the axioms

4.2 Properties of probability

The axioms of Definition 4.1 only gave us some of the properties that we would like a probability measure to have. Our task now (in this subsection and the next) is to carefully prove how these other properties follow from just those axioms. In particular, we're not allowed to make claims that merely “seem likely to be true” or “are common sense” – we can only use the three axioms together with strict logical deductions and nothing else.

Theorem 4.1. *Let Ω be a sample space with a probability measure \mathbb{P} . Then we have the following:*

1. $\mathbb{P}(\emptyset) = 0$.
2. $\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$ for all events $A \subset \Omega$.
3. For events A and B with $B \subset A$, we have $\mathbb{P}(B) \leq \mathbb{P}(A)$.
4. $0 \leq \mathbb{P}(A) \leq 1$ for all events $A \subset \Omega$.

Importantly, the second result here tells us how to deal with complements or “not” events: the probability of A *not* happening is 1 minus the probability it does happen. This is often very useful.

Proof. The key with most of these “prove from the axioms” problems is to think of a way to write the relevant events as part of a *disjoint* union, then use Axiom 3. Statements 1 and 2 are exercises for you on Problem Sheet 2. We’ll start with the third statement.

Here, since B is a subset of A , meaning that B is entirely inside A .

It would be useful to write A as a *disjoint* union of B and “the bit of A that isn’t in B ”. That is, we have the disjoint union

$$A = B \cup (A \cap B^c).$$

Applying Axiom 3 to this disjoint union gives

$$\mathbb{P}(A) = \mathbb{P}(B) + \mathbb{P}(A \cap B^c).$$

We’re happy to see the term on the left-hand side and the first term on the right-hand side. But what about the awkward $\mathbb{P}(A \cap B^c)$? Well, by Axiom 1,

we know that the probability of any event is greater than or equal to 0, so in particular. $\mathbb{P}(A \cap B^c) \geq 0$. Hence

$$\mathbb{P}(A) \geq \mathbb{P}(B) + 0 = \mathbb{P}(B),$$

and we are done with the third statement.

For the fourth statement, we have $\mathbb{P}(A) \geq 0$ directly from Axiom 1, so only need to show that $\mathbb{P}(A) \leq 1$. We can do this using the third statement of this theorem. For any event A we have $A \subset \Omega$, so the third statement tells us that $\mathbb{P}(A) \leq \mathbb{P}(\Omega)$. But Axiom 2 tells us that $\mathbb{P}(\Omega) = 1$, so $\mathbb{P}(A) \leq 1$ and we are done. \square

4.3 Addition rules for unions

If we have two or more events, we'd like to work out the probability of their union; that is, the probability that at least one of them occurs.

We already have an addition rule for *disjoint* unions.

Theorem 4.2. *Let $A, B \subset \Omega$ be two disjoint events. Then*

$$\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B).$$

Proof. In Axiom 3, take the finite sequence $A_1 = A, A_2 = B$. \square

But what about if A and B are not disjoint? Then we have the following.

Theorem 4.3. *Let $A, B \subset \Omega$ be two events. Then*

$$\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B).$$

You may have seen this result before. You've perhaps justified it by saying something like this: "We can add the two probabilities together, except now we've double-counted the overlap, so we have to take the probability of that away." Maybe you drew a Venn diagram. That's OK as a way to remember the result – but this is a proper university mathematics course, so we have to carefully *prove* it starting from just the axioms and nothing else.

(The following proof has been updated to match how I taught it in Wednesday's lecture.)

Proof. The problem here is that A and B are not (in general) disjoint, so we can't apply Axiom 3.

Instead, let's split this up into the three disjoint bits: “ A but not B ” $A \cap B^c$, “ B but not A ” $B \cap A^c$, and “both” $A \cap B$.

Now we can write A , B and $A \cup B$ in terms of these disjoint bits.

$$A = (A \cap B^c) \cup (A \cap B) \quad (4.1)$$

$$B = (B \cap A^c) \cup (A \cap B) \quad (4.2)$$

$$A \cup B = (A \cap B^c) \cup (B \cap A^c) \cup (A \cap B), \quad (4.3)$$

with all the unions on the right-hand side being disjoint. Applying Axiom 3 to them all gives

$$\mathbb{P}(A) = \mathbb{P}(A \cap B^c) + \mathbb{P}(A \cap B) \quad (4.4)$$

$$\mathbb{P}(B) = \mathbb{P}(B \cap A^c) + \mathbb{P}(A \cap B) \quad (4.5)$$

$$\mathbb{P}(A \cup B) = \mathbb{P}(A \cap B^c) + \mathbb{P}(B \cap A^c) + \mathbb{P}(A \cap B). \quad (4.6)$$

Here, (4.6) is looking good, but we need to get rid of the awkward $\mathbb{P}(A \cap B^c)$ and $\mathbb{P}(B \cap A^c)$ terms. We can do that by rearranging (4.4) and (4.5) to get

$$\mathbb{P}(A \cap B^c) = \mathbb{P}(A) - \mathbb{P}(A \cap B) \quad (4.7)$$

$$\mathbb{P}(B \cap A^c) = \mathbb{P}(B) - \mathbb{P}(A \cap B). \quad (4.8)$$

Substituting these into (4.6) gives

$$\mathbb{P}(A \cup B) = \mathbb{P}(A) - \mathbb{P}(A \cap B) + \mathbb{P}(B) - \mathbb{P}(A \cap B) + \mathbb{P}(A \cap B) \quad (4.9)$$

$$= \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B), \quad (4.10)$$

as required. \square

Example 4.3. Consider picking a card from a deck at random, with $\mathbb{P}(A) = |A|/52$. What's the probability the card is a spade or an ace?

It is possible to just work this out directly. But let's use our addition law for unions.

We have $\mathbb{P}(\text{spade}) = \frac{13}{52}$ and $\mathbb{P}(\text{ace}) = \frac{4}{52}$. So we have

$$\mathbb{P}(\text{spade or ace}) = \frac{13}{52} + \frac{4}{52} - \mathbb{P}(\text{spade and ace}).$$

But $\mathbb{P}(\text{spade and ace})$ is the probability of picking the ace of spades, which is $\frac{1}{52}$. Therefore

$$\mathbb{P}(\text{spade or ace}) = \frac{13}{52} + \frac{4}{52} - \frac{1}{52} = \frac{16}{52} = \frac{4}{13}.$$

Summary

- The axioms of probability are (1) $\mathbb{P}(A) \geq 0$; (2) $\mathbb{P}(\Omega) = 1$; and (3) that for disjoint events A_1, A_2, \dots , we have $\mathbb{P}(A_1 \cup A_2 \cup \dots) = \mathbb{P}(A_1) + \mathbb{P}(A_2) + \dots$.
- Other properties can be proven from these axioms, like the complement rule $\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$, and the addition rule for unions $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$.

Chapter 5

Classical probability I

5.1 Probability with equally likely outcomes

Classical probability is the name we give to probability where there are a finite number of equally likely outcomes.

Classical probability was the first type of probability to be formally studied – partly because it is the simplest, and partly because it was useful for working out how to win at gambling. Tossing fair coins, rolling dice, and dealing cards are all common gambling situations that can be studied using classical probability – in a deck of cards, for example, there are 52 cards that are equally likely to be drawn. Among the first works to seriously study classical probability were “Book on Games of Chance” by Girolamo Cardano (written in 1564, but not published until 1663, one hundred years later), and a famous series of letters between Blaise Pascal and Pierre de Fermat in 1654.

Definition 5.1. Let Ω be a finite sample space. Then the **classical probability measure** on Ω is given by

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|}.$$

So to work out a classical probability $\mathbb{P}(A)$, crucially we need to be able to count how many outcomes $|A|$ are in the event A and count how many outcomes $|\Omega|$ are in the whole sample space Ω . (This is why classical probability is also called “enumerative probability” – “enumeration” is another word for counting.) In this lecture and the next, we’ll look at some different ways in which we can count the number of outcomes in common events and sample spaces.

Example 5.1. *We roll a dice. What is the probability we get at least 5?*

The sample space is $\Omega = \{1, 2, 3, 4, 5, 6\}$, with $|\Omega| = 6$. The event that we roll at least 5 is $A = \{5, 6\}$, with $|A| = 2$. Hence

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{2}{6} = \frac{1}{3}.$$

There's something we ought to check before going any further!

Theorem 5.1. *Let Ω be a finite nonempty sample space. Then the classical probability measure on Ω ,*

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|},$$

is indeed a probability measure, in that it satisfies the three axioms in Definition 4.1.

Proof. We'll take the axioms one by one.

1. Since $|\Omega| \geq 1$ and $|A| \geq 0$, it is indeed the case that $\mathbb{P}(A) = |A|/|\Omega| \geq 0$.
2. We have $\mathbb{P}(\Omega) = \frac{|\Omega|}{|\Omega|} = 1$, as required.
3. Since we have a finite sample space, we only need to show Axiom 3 for a sequence of two disjoint events; the argument can be repeated to get any finite number of events. Let $A = \{a_1, a_2, \dots, a_k\}$ and $B = \{b_1, b_2, \dots, b_l\}$ be two disjoint events with $|A| = k$ and $|B| = l$. Note that we can enumerate the elements of the disjoint union $C = A \cup B$ as

$$c_1 = a_1, c_2 = a_2, \dots, c_k = a_k, c_{k+1} = b_1, c_{k+2} = b_2, \dots, c_{k+l} = b_l.$$

Since A and B are disjoint, this list has no repeats, and we see that $|C| = |A \cup B| = k + l$. Hence

$$\mathbb{P}(A \cup B) = \frac{k+l}{|\Omega|} = \frac{k}{|\Omega|} + \frac{l}{|\Omega|} = \mathbb{P}(A) + \mathbb{P}(B),$$

and Axiom 3 is fulfilled.

□

5.2 Multiplication principle

In classical probability, to find the probability of an event A , we need to count the number of outcomes in A and the total number of possible outcomes in Ω . This can be easy when we're just looking at one choice – like the 2 outcomes from tossing a single coin, the 6 outcomes of rolling a single dice, or the 52 outcomes from dealing a single card. Now we're going to look at what happens if there are a number of choices one after another – like tossing multiple coins, rolling more than one dice, or dealing a hand of cards.

Here, an important principle is the **multiplication principle**. The multiplication principle says that if you have n choices followed by m choices, then all together you have $n \times m$ total choices. You can see this by imagining the choices in a $n \times m$ grid, with the n columns representing the first choice and m rows representing the second choice. For example, suppose you go to a burger restaurant where there are 3 choices of burger (beefburger, chicken burger, veggie burger)

and 2 choices of sides (fries, salad), then altogether there are $3 \times 2 = 6$ choices of meal.

	Beefburger	Chicken burger	Veggie burger
Fries	1: Beefburger with fries	2: Chicken burger with fries	3: Veggie burger with fries
Salad	4: Beefburger with salad	5: Chicken burger with salad	6: Veggie burger with salad

More generally, if you have m stages of choosing, with n_1 choices in the first stage, then n_2 choices in the second stage, all the way to n_m choices in the final stage, you have $n_1 \times n_2 \times \cdots \times n_m$ total choices altogether.

Example 5.2. *Five fair coins are tossed. What is the probability they all show the same face?*

Here, the sample space Ω is the set of all sequences of 5 coin outcomes. How many sample outcomes are in Ω ? Well, the first coin can be heads or tails (2 choices); the second coin can be heads or tails (2 choices) and so on, until the fifth and final coin. So, by the multiplication principle, $|\Omega| = 2 \times 2 \times 2 \times 2 \times 2 = 2^5 = 32$.

The event we're interested in is $A = \{\text{HHHHH}, \text{TTTTT}\}$, the event that the faces are all the same – either all heads or all tails. This clearly has $|A| = 2$ outcomes.

So the probability all five coins show the same face is

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{2}{32} = \frac{1}{16} \approx 0.06.$$

Example 5.3. *Four dice are rolled. What is the probability we get at least one 6?*

Here, Ω is the set of all possible sequences of four dice rolls. Clearly $|\Omega| = 6^4 = 1296$.

The event A is the set of all dice roll sequences with at least one 6. Whenever you see a question with the phrase “at least one” in it, it's very often to look at the complementary event A^c instead. We know from the last section that $\mathbb{P}(A) = 1 - \mathbb{P}(A^c)$, but in “at least one” questions, it's often easier to count $|A^c|$ than to count $|A|$.

Here, since A is the set of all dice roll sequences with at least one 6, then A^c is the set of dice roll sequence without any 6s at all. This means all four dice must have rolled a 1, 2, 3, 4 or 5. Since each of the four dice rolls has five possibilities, this means that $|A^c| = 5^4 = 625$.

Putting this together, we see that

$$\mathbb{P}(A) = 1 - \mathbb{P}(A^c) = 1 - \frac{|A^c|}{|\Omega|} = 1 - \frac{625}{1296} = \frac{671}{1296} \approx 0.518.$$

So there's about a 52% chance we get at least one 6.

5.3 Sampling with and without replacement

Example 5.4. *A bag contains 15 balls: 10 black balls and 5 white balls. We draw 3 balls out of the bag. What is the probability all 3 balls are black (a) if we put each ball back into the bag after it is chosen; (b) if we do not put each ball back into the bag after it is chosen.*

Let's start with (a). The number of ways to choose a ball out 15 on three occasions is $|\Omega| = 15^3$. The number of ways to choose a black ball out of 10 on three occasions is $|A| = 10^3$. Hence

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{10^3}{15^3} = \frac{1000}{3375} = \frac{8}{27} \approx 0.30.$$

What about (b)? Here we don't put the ball back in the bag once it has been chosen. There are 15 ways to pick the first ball. But then there are only 14 balls left in the bag for the second choice, and only 13 balls for the third choice. So $|\Omega| = 15 \times 14 \times 13$. Similarly, there are 10 ways the first ball can be black. But once that black ball is removed, only 9 choices for the second black ball, and only 8 for the third. So $|A| = 10 \times 9 \times 8$. So this time we have

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{10 \times 9 \times 8}{15 \times 14 \times 13} = \frac{720}{2730} = \frac{24}{91} \approx 0.26,$$

which is smaller than the answer in part (a).

This example illustrated the difference between **sampling with replacement** (when the balls were put back into the bag) and **sampling without replacement** (when the balls were not put back). If we want to sample k items from a set of n items, then:

- the number of ways to sample with replacement is

$$n^k = n \times n \times \cdots \times n;$$

- the number of ways to sample without replacement is

$$n^{\underline{k}} = n \times (n-1) \times \cdots \times (n-k+1).$$

Here, we've defined the notation $n^{\underline{k}}$ for the number of ways to sample without replacement; this is called the **falling factorial** or **permutation number**. This is still k numbers multiplied together, but decreasing by 1 each time down from n . (Notice that the subscript is underlined in the falling factorial; other notation sometimes used includes $(n)_k$, $P(n, k)$, or ${}^n P_k$.)

Summary

- “Classical probability” describes the situation where there are finitely many equally likely outcomes. The classical probability $\mathbb{P}(A) = |A|/|\Omega|$ requires us to count how many outcomes there are in events or sample spaces.

- The multiplication principle says that n choices followed by m choices makes $n \times m$ choices in total.
- Sampling k objects out of n with replacement gives n^k choices.
- Sampling k objects out of n without replacement gives $n^{\underline{k}} = n(n-1) \dots (n-k+1)$ choices.

Chapter 6

Classical probability II

We continue looking at the classical probability $\mathbb{P}(A) = |A|/|\Omega|$, by looking at ways to enumerate Ω and A . Last time we saw:

- The multiplication principle: n_1 choices followed by n_2 choices, ..., up to n_k choices gives $n_1 \times n_2 \times \cdots \times n_k$ choices in total.
- Sampling k objects out of n with replacement gives n^k choices.
- Sampling k objects out of n without replacement gives $n^{\underline{k}} = n(n-1) \cdots (n-k+1)$ choices.

6.1 Ordering

Example 6.1. *Suppose a lecturer marks a pile of n exam papers, all of which receive a different mark. What is the probability she ends up marking them in order from lowest scoring first in the pile to highest scoring last in the pile?*

Here, the sample space Ω is the set of all orderings of the n exam papers by mark, and A is the event that the papers are in order from lowest to highest scoring. It's clear that $|A| = 1$: since the exams scored different marks, there's only one way of putting the exams in the correct lowest-to-highest order. But what's $|\Omega|$?

There are n choices for the first exam paper to be marked. Then, for the second exam paper, there are $n - 1$ choices left, because the lecturer is not going to mark the same paper twice. There are $n - 2$ choices for the third exam paper. And so on, until she has marked $n - 1$ papers, and there is only 1 choice left for the final paper. So we have

$$|\Omega| = n^{\underline{n}} = n(n-1)(n-2) \cdots 3 \cdot 2 \cdot 1 = n!$$

ways to order the exam papers.

Hence, the probability the papers are marked in order is

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{1}{n(n-1) \cdots 2 \cdot 1} = \frac{1}{n!}.$$

This number

$$n! = n^n = n(n-1)(n-2)\cdots 3 \cdot 2 \cdot 1$$

is called n **factorial** and denoted $n!$. It is the number of ways that n different objects can be ordered.

The factorial $n!$ gets very large very quickly. **Stirling's formula** gives the approximation $n! \approx \sqrt{2\pi n} e^{-n} n^n$.

Example 6.2. Suppose you shuffle a pack of cards. The resulting ordering of the deck has $52!$ possibilities. This is an unimaginably huge number – the exact value to 3 significant figures is

$$52! = 8.07 \times 10^{67},$$

while Stirling's formula gives the approximation

$$52! \approx \sqrt{2\pi \times 52} \times e^{-52} \times 52^{52} = 8.05 \times 10^{67}.$$

This is an 8 followed by 67 zeroes.

If every person on the planet had shuffled a deck of cards one million times a second for the entire lifetime of the universe, they could only expect to have got through about 10^{33} shuffles. This is only the most tiny, microscopic fraction of $52!$. So every time you have ever shuffled a deck of cards, it is essentially certain that you have created an ordering of the deck that has never existed before.

It can sometimes be useful to write the falling factorial $n^{\underline{k}}$ in terms of the factorial, like this:

$$\begin{aligned} n^{\underline{k}} &= n(n-1)\cdots(n-k+1) \\ &= n(n-1)\cdots(n-k+1) \times \frac{(n-k)(n-k-1)\cdots 2 \cdot 1}{(n-k)(n-k-1)\cdots 2 \cdot 1} \\ &= \frac{n(n-1)\cdots(n-k+1)(n-k)(n-k-1)\cdots 2 \cdot 1}{(n-k)(n-k-1)\cdots 2 \cdot 1} \\ &= \frac{n!}{(n-k)!}, \end{aligned}$$

where the numbers from $n-k$ down to 1 cancel out.

6.2 Sampling without replacement in any order

Example 6.3. In the Lotto, the UK national lottery, you can buy a ticket for £2 and choose 6 numbers between 1 and 59. If your 6 numbers match the 6 numbers on the balls chosen by the lottery machine, you win the jackpot (usually between £2 million and £20 million, shared between the tickets that get all 6 numbers). If you buy a ticket, what is the probability you win the jackpot?

Here, Ω is the set of all possible sets of 6 winning numbers, and A is the set of numbers on your ticket. Clearly $|A| = 1$, but what is $|\Omega|$?

Well, the first ball out of the machine has 59 possibilities, the second ball has 58 possibilities, and so on, making

$$59 \times 58 \times 57 \times 56 \times 55 \times 54 = 59^6.$$

But this isn't the correct answer, because the same set of balls could be drawn from the machine in any order! The sets of balls $\{1, 2, 3, 4, 5, 6\}$ and $\{1, 2, 3, 4, 6, 5\}$ and $\{6, 5, 4, 3, 2, 1\}$ are all the same set of numbers. How many ways can we see the same list of numbers? This is precisely the number of orderings of 6 balls, which we know is $6!$. So the number of possible sets of 6 balls to come out of the machine is actually

$$\binom{59}{6} = \frac{59^6}{6!} = \frac{59 \times 58 \times 57 \times 56 \times 55 \times 54}{6 \times 5 \times 4 \times 3 \times 2 \times 1} \approx 45 \text{ million}.$$

Thus the probability that your ticket wins the jackpot is

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{1}{\binom{59}{6}} \approx \frac{1}{45 \text{ million}} \approx 0.00000002.$$

Here, we have introduced the notation

$$\binom{n}{k} = \frac{n^k}{k!} = \frac{n(n-1) \cdots (n-k+1)}{k(k-1) \cdots 2 \cdot 1}$$

for the number of ways to choose k objects out of n without replacement *and where the order they were chosen in doesn't matter*. This is called the **binomial coefficient**, although when we say it out loud we normally just say “ n choose k ”. (Another notation for the binomial coefficient is nC_k .)

It can sometimes be useful to remember that $n^k = n!/(n-k)!$ allows us to write the binomial coefficient in terms of the factorial function as

$$\binom{n}{k} = \frac{n^k}{(n-k)!} = \frac{n!}{k!(n-k)!}.$$

Example 6.4. You are dealt a “hand” of 13 cards from a deck of 52 cards. What is the probability that you have the Ace, King, Queen, and Jack of Spades?

Here, Ω is the set of all 13-card hands from the deck, and A is the subset of those that contain the AKQJ of Spades.

Using the binomial coefficient notation, it's clear that

$$|\Omega| = \binom{52}{13} = \frac{52 \times 51 \times \cdots \times 41 \times 40}{13 \times 12 \times \cdots \times 2 \times 1}.$$

What about $|A|$? If we fix the fact that the hand contains the 4 cards AKQJ of Spades, then it also contains $13 - 4 = 9$ cards out of the other $52 - 4 = 48$ remaining cards in the deck. This makes

$$|A| = \binom{48}{9} = \frac{48 \times 47 \times \cdots \times 41 \times 40}{9 \times 8 \times \cdots \times 2 \times 1}$$

hands.

Thus the probability that the hand contains AKQJ of Spades is

$$\mathbb{P}(A) = \frac{|A|}{|\Omega|} = \frac{\binom{48}{9}}{\binom{52}{13}}.$$

Conveniently, we can simplify the expression quite a lot, because plenty of cancellation will occur. We have

$$\begin{aligned} \mathbb{P}(A) &= \frac{\binom{48}{9}}{\binom{52}{13}} = \frac{\frac{48 \times 47 \times \cdots \times 41 \times 40}{9 \times 8 \times \cdots \times 2 \times 1}}{\frac{52 \times 51 \times \cdots \times 41 \times 40}{13 \times 12 \times \cdots \times 2 \times 1}} \\ &= \frac{48 \times 47 \times \cdots \times 41 \times 40}{52 \times 51 \times \cdots \times 41 \times 40} \times \frac{13 \times 12 \times \cdots \times 2 \times 1}{9 \times 8 \times \cdots \times 2 \times 1} \\ &= \frac{13 \times 12 \times 11 \times 10}{52 \times 51 \times 50 \times 49} \\ &\approx 0.0026, \end{aligned}$$

or about 1 in every 380 hands.

6.3 Birthday problem

There are $k = 23$ students in a class. What is the probability that at least two of the students share a birthday?

This is a famous problem, known as the “birthday problem”. You may have seen this problem before. But let’s try to solve it using the techniques from this section of notes. (We’ll assume all days are equally likely for birthdays, and ignore the leap day 29 February.)

The sample space $|\Omega|$ is the set of possible birthdays for the k students. Clearly $|\Omega| = 365^k$.

Let A be the event that at least two students share a birthday. Since this is an “at least” event, it seems like it might be a good idea to look instead at the complement event A^c instead. If A is the event that there’s at least one shared birthday, then A^c is the event that there are *no* shared birthdays; that is, A^c is the event that all k students have *different* birthdays.

So what is $|A^c|$, the number of ways the k students can have different birthdays? Well, the first student can have any of the 365 days for their birthday. For them to have different birthdays, the second student only has 364 days available. Then the third student must avoid the birthday of students 1 and 2, so has 363 available days, and so on. We see that

$$|A^c| = 365 \times 364 \times \cdots \times (365 - k + 1) = 365^k.$$

Hence, the probability at least two students share a birthday is

$$\mathbb{P}(A) = 1 - \mathbb{P}(A^c) = 1 - \frac{365^k}{365^k} = 1 - \frac{365}{365} \cdot \frac{364}{365} \cdots \frac{365 - k + 1}{365}.$$

Setting $k = 23$, we can calculate the required answer in R:

```
k <- 23
1 - prod((365:(365 - k + 1)) / 365)
```

```
## [1] 0.5072972
```

The probability is 50.7%. So it's more likely than not that at least two students share a birthday.

Some people find it surprising that only 23 students have such a high probability of sharing a birthday, since 23 is so small compared to 365. But remember there are $\binom{23}{2} = 253$ *pairs* of birthdays, and each of those 253 pairs is a potential match.

Summary

- Ordering n objects can be done in $n! = n^n = n(n-1) \dots 2 \cdot 1$ ways.
- The number of ways to sample k objects out of n when the order doesn't matter is given by the binomial coefficient $\binom{n}{k} = n^k/k!$.

Problem Sheet 2

You can download this problem sheet as a PDF file

This is Problem Sheet 2. This problem sheet covers material from Lectures 3 to 6. You should work through all the questions on this problem sheet in preparation for your tutorial in Week 4. The problem sheet contains two assessed questions, which are due in by **2pm on Monday 31 October**.

A: Short questions

A1. Suppose you toss a coin 4 times.

(a) What would you suggest for a sample space Ω (i) if you only care about the total number of heads; (ii) if you care about the result of each coin toss?

(b) For each of the cases in part (a), what is $|\Omega|$?

A2. Let A , B and C be events in a sample space Ω . Write the following events using only A , B , C and the complement, intersection, and union operations.

(a) C happens but A doesn't.

(b) At least one of A , B and C happens.

(c) Exactly one of B or C happens.

(d) Exactly two of A , B and C happens.

A3. What is the value of the following expressions?

(a) $6!$

(b) 8^4

(c) 8^4

(d) $\binom{10}{4}$

A4. An urn contains 4 red balls and 6 blue balls. Two balls are drawn from the urn. What is the probability that both balls are red, if the balls are drawn

(a) with replacement; (b) without replacement?

B: Long questions

B1. Starting from just the three probability axioms, prove the following statements:

(a) $\mathbb{P}(\emptyset) = 0$.

(b) $\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$.

B2. In this question, you will have to use the standard two-event form of the addition rule for unions

$$\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B).$$

(a) Using the two-event addition rule, show that

$$\mathbb{P}(C \cup D \cup E) = \mathbb{P}(C) + \mathbb{P}(D \cup E) - \mathbb{P}(C \cap (D \cup E)).$$

(b) Using your result from part (a), the two-event addition rule, the distributive law, and the two-event addition rule again, prove the three-event form of the addition rule for unions:

$$\mathbb{P}(C \cup D \cup E) = \mathbb{P}(C) + \mathbb{P}(D) + \mathbb{P}(E) - \mathbb{P}(C \cap D) - \mathbb{P}(C \cap E) - \mathbb{P}(D \cap E) + \mathbb{P}(C \cap D \cap E).$$

B3. Suppose we pick a number at random from the set $\{1, 2, \dots, 2022\}$.

(a) What is the probability that the number is divisible by 5?

(b) What is the probability the number is divisible by 5 or by 7?

B4. Eight friends are about to sit down at random at a round table. Find the probability that

(a) Ashley and Brook sit next to each other, with Chris directly opposite Brook;

(b) neither Ashley, Brook nor Chris sit next to each other.

B5. A “random digit” is a number chosen at random from $\{0, 1, \dots, 9\}$, each with equal probability. A statistician chooses n random digits (with replacement).

(a) For $k = 0, 1, \dots, 9$, let A_k be the event that all the digits are k or smaller. What is the probability of A_k , as a function of k and n ?

(b) Let B_k be the event that the largest digit chosen is equal to k . By finding a relationship between B_k , A_{k-1} and A_k , or otherwise, show that

$$\mathbb{P}(B_k) = \frac{(k+1)^n - k^n}{10^n}.$$

C: Assessed questions

The last two questions are **assessed questions**. These two questions count for 3% of your final mark for this module.

The deadline for submitting your solutions is **2pm on Monday 31 October** at the beginning of Week 5. Submission is via Gradescope. Your work will be marked by your tutor and returned on Monday 7 November, when solutions will also be made available.

Both questions are “long questions”, where the marks are not only for mathematical accuracy but also for the clarity and completeness of your explanations.

You should not collaborate with others on the assessed questions: your answers must represent solely your own work. The University’s rules on academic integrity – and the related punishments for violating them – apply to your work on the assessed questions.

C1. Let Ω be a sample space with a probability measure \mathbb{P} , and let $A, B \subset \Omega$ be events. For each of the following statements, state whether the statement is true or false (that is, always true or sometimes false). If it is true, briefly justify the statement; if it is false, give a counterexample.

- (a) If $\mathbb{P}(A) \leq \mathbb{P}(B)$, then $A \subset B$.
- (b) $\mathbb{P}(A \cap B) + \mathbb{P}(A \cap B^c) = \mathbb{P}(A)$.
- (c) $\mathbb{P}(A \cup B) \leq \mathbb{P}(A)$
- (d) If A and B are disjoint, then $\mathbb{P}((A \cup B)^c) = 1 - \mathbb{P}(A) - \mathbb{P}(B)$.

C2. An urn contains 15 balls: 4 red balls, 5 blue balls, and 6 green balls.

- (a) If three balls are drawn *with* replacement, what is the probability that all three balls are the *same* colour?
- (b) If three balls are drawn *without* replacement, what is the probability that all three balls are *different* colours?

Solutions to short questions

- A1.** (a) (i) $\{0, 1, \dots, 4\}$ (ii) $\{\text{HHHH}, \text{HHHT}, \text{HHTH}, \dots, \text{TTTT}\}$ (b) (i) 5 (ii) 16.
A2. (a) $C \cap A^c$ (b) $A \cup B \cup C$ (c) $(B \cup C) \cap (B \cap C)^c$ or $(B \cap C^c) \cup (B^c \cap C)$
 (d) $(A \cap B \cap C^c) \cup (A \cap B^c \cap C) \cup (A^c \cap B \cap C)$ or other equivalent
A3. (a) 720 (b) 4092 (c) 1680 (d) 210
A4. (a) 0.16 (b) 0.133

Other stuff

R Worksheets

R worksheets

Each week there will be an R worksheet to work through in your own time. I recommend spending about one hour on each worksheet, plus one extra hour for worksheets with assessed questions, for checking and submitting your solutions.

Week	Worksheet	Deadline for assessed work
1	R basics (Solutions)	—
2	Vectors	—
3	Data in R	Monday 24 October (Week 4)
4	Plots I: Making plots	—
5	Plots II: Making plots better	Monday 7 November (Week 6)
6	RMarkdown (optional)	—
7	Discrete distributions	Monday 21 November (Week 8)
8	Discrete random variables	—
9	Normal distribution	Monday 5 December (Week 10)
10	Law of large numbers	—
11	Recap	Thursday 15 December (Week 11)

About R and RStudio

- **R** is a *programming language* that is particularly useful for working with probability and statistics. R is very widely used in universities and increasingly widely used in industry. Learning to use R is a mandatory part of this module, and exercises requiring use of R make up at least 15% of your module mark. Many other statistics-related modules at the University also use R.
- **RStudio** is a *program* that gives a convenient way to work with the language R. RStudio is the most common way to use the language R, and learning to use RStudio is strongly recommended.

R and RStudio are free/open-source software.

How to access R and RStudio

There are a few ways you can access R and RStudio.

First, you can **install R and RStudio on your own computer**. Students who have their own computer (with administration and installation rights) usually find this the most convenient way use R.

When you install R and RStudio, it's important that you install R (the programming language) first, and only install RStudio (the program to use R) after R has already been installed. This ensures that RStudio can “find” R on your computer.

1. *First*, install R. Go to the Comprehensive R Archive Network (CRAN) and follow the instructions:
 - Windows: Click “Download R for Windows”, then “Install R for the first time”. The main link at the top should be to download the most recent version of R.
 - Mac: Click Download R for macOS, and then download the relevant PKG file. (For typically older Intel-based Macbooks, you must use the “Intel 64-bit build”; for post-November 2020 M1 or M2-based “Apple silicon” Macbooks, the “Apple silicon arm64 build” may be slightly faster.)
2. *After* R is installed, *then* install RStudio. Go to the Download page at RStudio.com and follow the instructions. You want “RStudio Desktop”, and you want the free version.

If you have difficulty installing R, come along to the R troubleshooting drop-in session in Week 2 and bring your computer with you (if it's sufficiently portable), and we'll do our best to help.

Second, you can **use R and RStudio on University computers**. All University computers have access to R and RStudio, via the AppsAnywhere service. *First*, launch R via AppsAnywhere (at the time of writing, it's confusingly named “Cran R 4.2.0 x64”). You can then close the program that opens. *Then* launch RStudio (“Rstudio 2022”), also via AppsAnywhere.

The R drop-in sessions take place in computer rooms, so if you have problems accessing R and RStudio on University computers, you can get help at the drop-in sessions too.

Third, you can **use the RStudio Cloud**. The RStudio Cloud is a cloud-hosted “Google Docs for R” that you can use through your web browser, without having to install anything. You can get 25 hours per month for free, which should be plenty for this module, or pay for more.

If you have access to a computer on which you can't install software, such as some Chromebooks or tablet computers, or if you're borrowing a friend's laptop, the RStudio Cloud can be a convenient solution.

Update: If you have an Intel-based Chromebook, then we have had success installing R and RStudio using these instructions.

R troubleshooting drop-in sessions

You will learn to use R by working through the R Worksheets. Learning to use a programming language is different from learning mathematics: you should expect to regularly get frustrated and annoyed when the computer seems to refuse to do what you want it to (but also occasionally experience the joy of getting it right!). This is a normal part of learning.

However, many students find getting with started with R in the first few weeks particularly difficult. Also, sometimes students have problems installing R and RStudio on their own computers. To help with this, we have organised optional R troubleshooting drop-in sessions in Weeks 2 and 3. Check your timetable for details – they are probably listed as “computer practicals”.

Solutions

This page has the solutions to all the non-assessed questions on Problem Sheet 1 to 5. Solutions are added after tutorials on the Problem Sheet have finished.

Solutions to assessed questions are available on Minerva in the “Assessments” tab, from one week after the deadline.

There are many ways you get feedback on this module, both group feedback (feedback that is generally relevant to many people) and individual feedback (feedback based specifically on your own approach to the work).

- You will have received both individual and group spoken feedback in your tutorial (the more you speak up in your tutorial, the more individualised the feedback you get in return).
- These solutions include group written feedback on common issues for the class.
- Most importantly, when your work on assessed questions is marked, individual written feedback will be given via the Gradescope site. It is very important that you read that feedback.
- Finally, students who would like even more feedback can discuss their work with me in the “office hours” drop-in sessions.

Problem Sheet 1

A1. Consider again the “number of Skittles in each packet” data from Example 1.1.

59, 59, 59, 59, 60, 60, 60, 61, 62, 62, 62, 63, 63.

(a) Calculate the mean number of Skittles in each packet.

Solution. This was in the notes:

$$\bar{x} = \frac{1}{13}(59 + 59 + \dots + 63) = \frac{789}{13} = 60.7.$$

(b) Calculate the sample variance using the computational formula.

Solution.

$$\begin{aligned}s_x^2 &= \frac{1}{13-1} ((59^2 + 59^2 + \dots + 63^2) - 13 \times 60.6923^2) \\ &= \frac{1}{12} (47915 - 47886.2) \\ &= 2.40\end{aligned}$$

Group feedback: With the computational formula, the value $\sum_i x_i^2 - n\bar{x}^2$ is typically a fairly small number given as the difference between two very big numbers $\sum_i x_i^2$ and $n\bar{x}^2$. This means you have to get the two big numbers very precise, to ensure the cancellation happens correctly; in particular, make sure you use plenty of decimal places of accuracy in \bar{x} .

(c) Calculate the sample variance using the definitional formula.

Solution.

$$\begin{aligned}s_x^2 &= \frac{1}{13-1} ((59-60.7)^2 + (59-60.7)^2 + \dots + (63-60.7)^2) \\ &= \frac{1}{12} (2.86 + 2.86 + \dots + 5.33) \\ &= \frac{1}{12} \times 28.77 \\ &= 2.40\end{aligned}$$

(d) Out of (b) and (c), which calculation did you find easier, and why?

Solution. The computational formula required fewer presses of the calculator buttons, because $\sum_i x_i^2$ is fewer button-presses than $\sum_i (x_i - \bar{x})^2$, where you have to subtract the means before squaring.

On the other hand, the expression inside the brackets of the computational formula is a fairly small number given as the difference of two very large numbers, so it was necessary to use lots of decimal places of accuracy in \bar{x} to make sure the second large number was accurate and therefore that the subtraction cancelled correctly.

Group feedback: Many answer for (d) are fine provided you give a justification.

A2. Consider the following data sets of the age of elected politicians on a local council. (The “18–30” bin, for example, means from one’s 18th birthday to the moment before one’s 30th birthday, so lasts 12 years.)

Age (years)	Frequency	Relative frequency	Frequency density
18–30	1		
30–40	3		
40–45	4		
45–50	5		
50–55	3		
55–60	1		

Age (years)	Frequency	Relative frequency	Frequency density
60–70	3		
Total	20	1	—

(a) Complete the table by filling in the relative frequency and frequency densities.

Solution.

Age (years)	Frequency	Relative frequency	Frequency density
18–30	1	0.05	0.0041
30–40	3	0.15	0.015
40–45	4	0.2	0.04
45–50	5	0.25	0.05
50–55	3	0.15	0.03
55–60	1	0.05	0.01
60–70	3	0.15	0.015
Total	20	1	—

(b) What is the median age bin?

Solution. The 10th- and 11th-largest observations are both in the 45–50 bin, which is therefore the median bin.

(c) What is the modal age bin?

Solution. The bin with the largest frequency density is 45–50, which is therefore the modal bin.

(d) Calculate (the standard approximation of) the mean age of the politicians.

Solution. Pretending that each person is in the centre of their bin, we have

$$\bar{x} = \frac{1}{20}(1 \times 24 + 3 \times 35 + \cdots + 3 \times 65) = \frac{946.5}{20} = 47.3.$$

A3. Consider the two datasets illustrated by the boxplots below. Write down some differences between the two datasets.

Solution. Some answers could be:

- The median and inter-quartile range of Dataset 2 appear to be very slightly larger than those in Dataset 1, although the differences are very small and might not be important in real life.
- Dataset 2 has a few outliers; Dataset 1 has none.
- While Dataset 1 is fairly “balanced” either side of the median, Dataset 2 shows what statisticians call a “positive skew”: the data above the median is much more spread out than the data below the median.

Group feedback: You can probably think of other answers.

B1. For each of the two datasets below, calculate the following summary statistics, or explain why it is not possible to do so: mode; median; mean; number of distinct outcomes; inter-quartile range; and sample variance.

(a) Six packets of Skittles are opened together, and the total number of sweets of each colour is:

Colour	Red	Orange	Yellow	Green	Purple
Number of Skittles	67	71	87	74	62

Solution. The modal colour is Yellow. The number of distinct outcomes is 5.

It's not possible to calculate the median or the quartiles, because, unlike numerical data, the colours can't be put "in order" from smallest to largest.

It's not possible to calculate the mean or sample variance, as these require us to have numerical data that can be "added up", but this can't be done with colours.

(b) Shirt sizes for a university football squad:

Colour	Xtra Small	Small	Medium	Large	Xtra Large
Number of shirts	0	1	6	4	5

Solution. The modal shirt size is medium. The number of distinct outcomes is 4 (we don't quite "Xtra Small", which was not observed in the data).

This time, we can order the data from smallest to largest, even though the data is not numerical. Since $(16 + 1)/2 = 8.5$, the median datapoint is the 8th or 9th datapoints, which are Large.

Since $1 + 0.25(16 - 1) = 4.75$ the lower quartile is the 4th or 5th datapoints, which are Medium. Since $1 + 0.75(16 - 1) = 12.25$, the upper quartile is the 12th or 13th datapoints, which are Xtra Large. So we can certainly say that the inner quartiles range from Medium to Xtra Large. We could probably also say that the interquartile range is 3 shirt sizes (Medium, Large, Xtra Large).

Again, because the data is not numerical, we can't add it up, so can't calculate a mean or sample variance.

Group feedback: Make sure your explanation is clear for why we can't calculate a median for the Skittles data but can for the shirts: the key is whether or not the data can be *ordered*.

B2. A summary statistic is informally said to be "robust" if it typically doesn't change much if a small number of outliers are introduced to a large dataset, or "sensitive" if it often changes a lot when a small number of outliers are introduced. Briefly discuss the robustness or sensitivity of the following summary statistics: (a) mode; (b) median; (c) mean; (d) number of distinct outcomes; (e) inter-quartile range; and (f) sample variance.

Solutions.

(a) The mode will typically not change at all if a small number of outliers are introduced, so is robust. (The exception is for data where every observation is likely to be different, so the outliers become "joint modes" along with everything else; but in this case the mode is not a useful statistic in the first place.)

(b) The introduction of outliers will typically only change the median a little bit, by shifting it between different nearby values in the "central mass" of the data. In particular, the *size* of the outliers won't make any difference at all (only whether they are "high outliers" above the median or "low outliers" below the median). So the median is robust.

(c) The mean can change a lot if outliers are introduced, especially if the outlier is enormously far out from the data. So the mean is sensitive.

(d) The number of distinct outcomes will only increase by (at most) 1 for each outlier introduced, so is robust.

(e) The interquartile range is robust, for the same reason as the median.

(f) The sample variance is sensitive, for the same reason as the mean.

(You might like to think about situations where it's better to use a robust statistic or better to use a sensitive statistic.)

Group feedback: I find it helpful to suppose I was studying the net worth of people in my tutorial group, and calculating summary statistics. How would those statistics change if Elon Musk (founder of Tesla, net worth roughly \$200 billion) joined my tutorial group?

Remember that “robust” and “sensitive” are general descriptions rather than precise mathematical definitions. So it doesn't matter if you disagree with my opinions provided that you give clear and detailed explanations to back up your opinion.

B3. Let $\mathbf{a} = (a_1, a_2, \dots, a_n)$ and $\mathbf{b} = (b_1, b_2, \dots, b_n)$ be two real-valued vectors of the same length. Then the *Cauchy–Schwarz inequality* says that

$$\left(\sum_{i=1}^n a_i b_i \right)^2 \leq \left(\sum_{i=1}^n a_i^2 \right) \left(\sum_{i=1}^n b_i^2 \right).$$

(a) By making a clever choice of (a_i) and (b_i) in the Cauchy–Schwarz inequality, show that $s_{xy}^2 \leq s_x^2 s_y^2$.

Solutions. Recalling the formulas for s_{xy} , s_x^2 , and s_y^2 ,

$$\begin{aligned} s_{xy} &= \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}), \\ s_x^2 &= \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2, \\ s_y^2 &= \frac{1}{n-1} \sum_{i=1}^n (y_i - \bar{y})^2, \end{aligned}$$

and comparing them with the Cauchy–Schwarz inequality, it looks like taking $a_i = x_i - \bar{x}$ and $b_i = y_i - \bar{y}$ might be useful. Making the substitution, we get

$$\left(\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}) \right)^2 \leq \left(\sum_{i=1}^n (x_i - \bar{x})^2 \right) \left(\sum_{i=1}^n (y_i - \bar{y})^2 \right).$$

These are very close to the formulas for s_{xy} , s_x^2 , and s_y^2 , but are just missing the “ $1/(n-1)$ ”s; what we in fact have is

$$((n-1)s_{xy})^2 \leq (n-1)s_x^2 \cdot (n-1)s_y^2.$$

Cancelling $(n-1)^2$ from each side, we have $s_{xy}^2 \leq s_x^2 s_y^2$.

(b) Hence, show that the correlation r_{xy} satisfies $-1 \leq r_{xy} \leq 1$.

Solutions. Recall the formula for the correlation is

$$r_{xy} = \frac{s_{xy}}{s_x s_y}.$$

We can make part (a) look a bit like this dividing both sides by $s_x^2 s_y^2$, to get

$$\frac{s_{xy}^2}{s_x^2 s_y^2} \leq 1.$$

In fact that's the square of the correlation on the left-hand side, so we've shown that $r_{xy}^2 \leq 1$.

Finally, we note that if a number squared is less than or equal to 1, then the number must be between -1 and +1 inclusive. (Numbers bigger than 1 get bigger still when squared; number smaller than -1 become bigger than +1 when squared.) Hence we have shown that $-1 \leq r_{xy} \leq 1$, as required.

Group feedback: In part (b) there's a temptation to "square-root both sides of the inequality". But you have to be very careful when you do this – make sure you are properly accounting for the positive and negative square roots on both side (if necessary), and where that does or doesn't require reversing the inequality. I recommend leaving the square-root operation until the last possible moment of the proof or, perhaps even better, reasoning through words as I did above.

Remember that you can still attempt part (b) even if you got stuck on part (a).

B4. A researcher wishes to study the effect of mental health on academic achievement. The researcher will collect data on the mental health of a cohort of students by asking them to fill in a questionnaire, and will measure academic achievement via the students' scores on their university exams. Discuss some of the ethical issues associated with the collection, storage, and analysis of this data, and with the publication of the results of the analysis. Are there ways to mitigate these issues?

(It's not necessary to write an essay for this question – a few short bulletpoints will suffice. There may be an opportunity to discuss these issues in more detail in your tutorial.)

Group feedback: There are no "correct" or "incorrect" answers here, but here are a few things that students in my own tutorials brought up, which may act as a prompt for your own discussions.

- It's important the students/subjects have given their consent for their data to be used this way. It must be "informed consent", where they understand for what purpose the data will be used, how it will be stored, and so on. It must be easy and painless for students to decline to take part.

- Consideration should be given on how to anonymise the data as much as possible – it’s not necessary for those analysing the data to know which questionnaire or which exam result belongs to which student, only that the questionnaire and results can be paired up.
- Even if after data is anonymised, care should be taken about whether the students could be worked out from the data. For example, if only one student did a certain combination of modules, their identity could “leak” that way. Perhaps imprecise data, such as classes rather than exact marks, might help while only slightly reducing the usefulness of the data?
- On one hand, it seems like this data should perhaps be deleted once analysis has been carried out, for the privacy of the students. On the other hand, principles of “open science” suggest that the data should be kept – and even publically made available – for other researchers to check the work. There are competing ethical considerations here.
- If correlations are found in the data, care should be taken when publishing the analysis not to wrongly suggest a causation. (Just because X and Y are positively correlated, it doesn’t mean that X *causes* Y – or that Y causes X.)

You can probably think of many other things.
